STACK

✂ Stack is an abstract data type with a predefined capacity.

✂ A stack is a linear data structure.

✂ A stack is an ordered collection of data elements where the insertion and deletion operations take place at one end only

✂ Its called Last In First Out()

✂ It is a simple data structure that allows adding and removing elements in a particular order.

✂ Every time an element is added, it goes on the top of the stack, the only element that can be removed is the element that was at the top of the stack, just like a pile of objects.
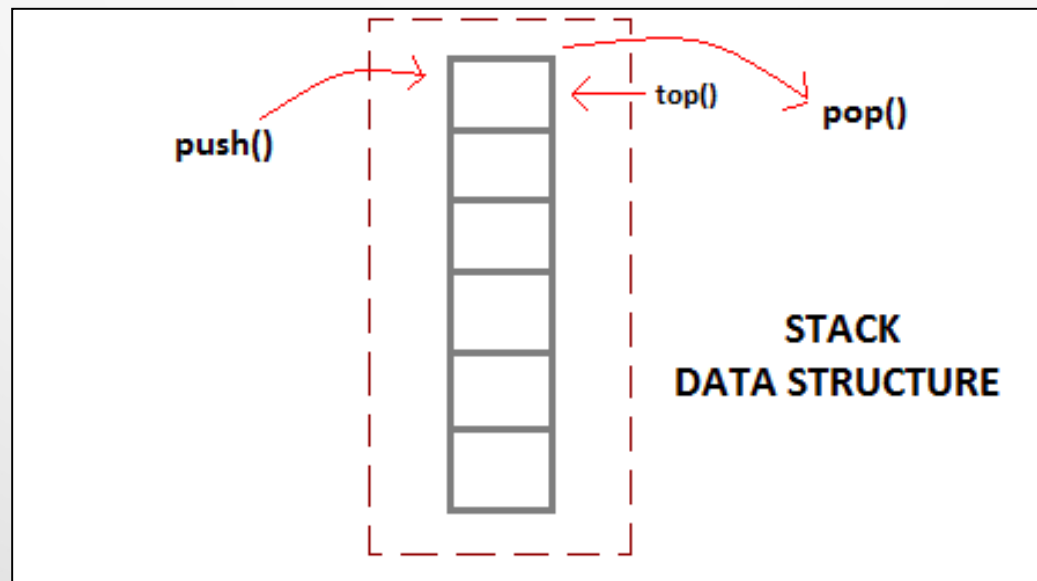

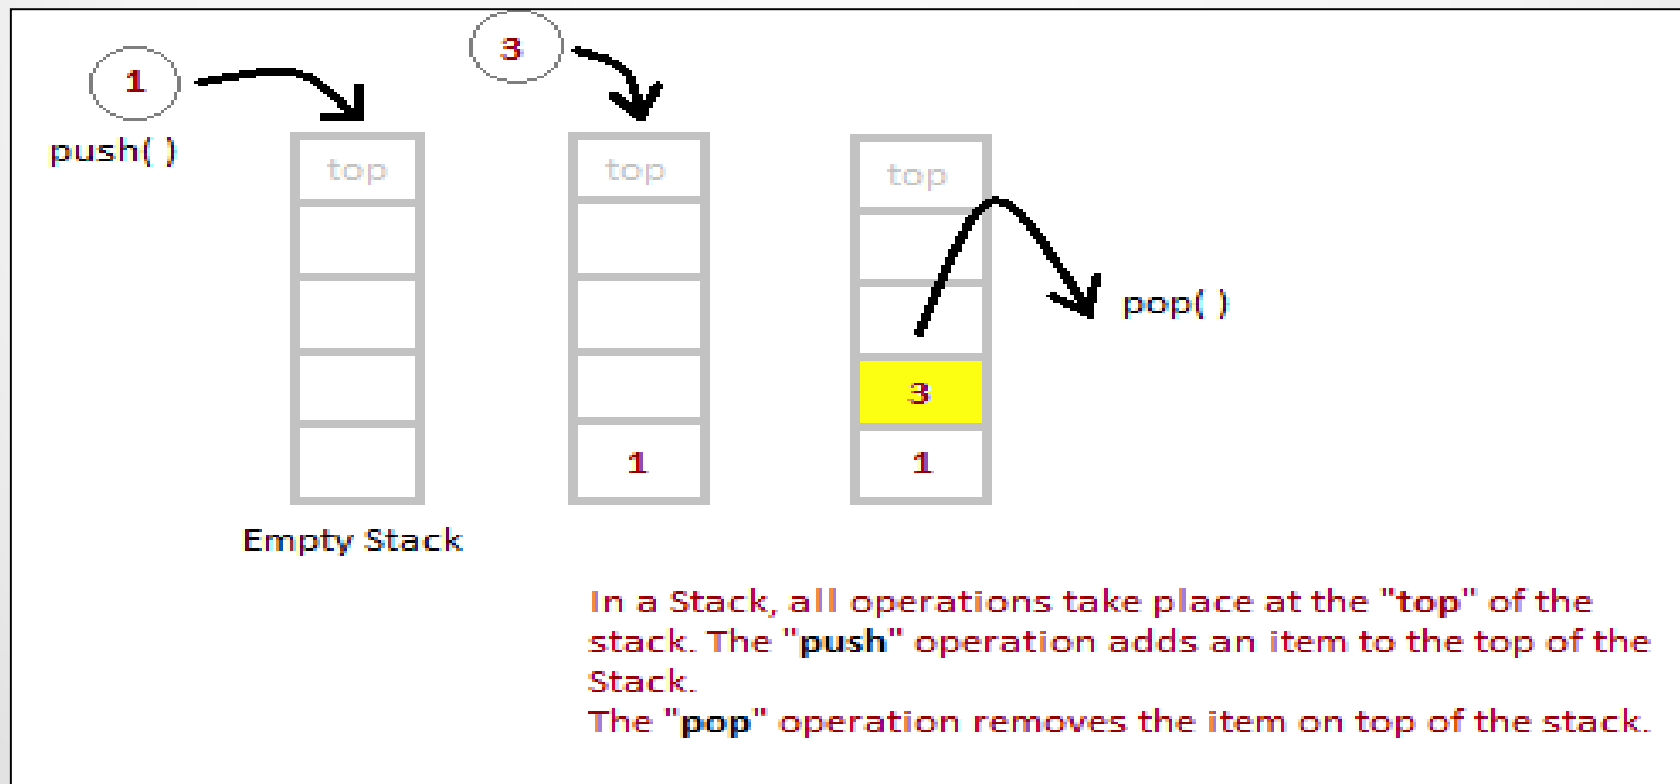

Stack
Basic features of Stack

✂ Stack is an ordered list of similar data type.

✂ Stack is a LIFO structure. (Last in First out).

✂ push() function is used to insert new elements into the Stack and pop() is used to delete an element from the stack. Both insertion and deletion are allowed at only one end of Stack called Top.

✂ Stack is said to be in Overflow state when it is completely full and is said to be in Underflow state if it is completely empty.
Implementation of Stack

✂Stack can be easily implemented using an Array or a Linked List.
✂Arrays are quick, but are limited in size and Linked List requires overhead to allocate, link, unlink, and deallocate, but is not limited in size. Here we will implement Stack using array.

Array-based implementation

✂ In an array-based implementation we maintain the following fields: an array A of a default size (≥ 1), the variable top that refers to the top element in the stack and the capacity that refers to the array size.

Linked List-based implementation

✂Linked List-based implementation provides the best (from the efficiency point of view) dynamic stack implementation.
Basic Operations

✂ A stack is used for the following two primary operations −
 - **push()** − pushing (storing) an element on the stack.
 - **pop()** − removing (accessing) an element from the stack.

✂ To use a stack efficiently we need to check status of stack as well. For the same purpose, the following functionality is added to stacks −
 - **peek()** − get the top data element of the stack, without removing it.
 - **isFull()** − check if stack is full.
 - **isEmpty()** − check if stack is empty.

✂ At all times, we maintain a pointer to the last PUSHed data on the stack. As this pointer always represents the top of the stack, hence named top. The top pointer provides top value of the stack without actually removing it.

PUSH Operation

✂ The process of putting a new data element onto stack is known as PUSH Operation. Push operation involves series of steps −

- Step 1 − Check if stack is full.
- Step 2 − If stack is full, produce error and exit.
- Step 3 − If stack is not full, increment top to point next empty space.
- Step 4 − Add data element to the stack location, where top is pointing.
- Step 5 − return success.
POP Operation

✂Accessing the content while removing it from stack, is known as pop operation.

✂In array implementation of pop() operation, data element is not actually removed, instead top is decremented to a lower position in stack to point to next value. But in linked-list implementation, pop() actually removes data element and deallocates memory space.

✂A POP operation may involve the following steps −
- Step 1 − Check if stack is empty.
- Step 2 − If stack is empty, produce error and exit.
- Step 3 − If stack is not empty, access the data element at which top is pointing.
- Step 4 − Decrease the value of top by 1.
- Step 5 − return success.
Pop Operation

Basic Operations: Push & Pop

Algorithm for PUSH Operation

Step 1: If TOP >= SIZE – 1 then

       Write "Stack is Overflow"

Step 2: TOP = TOP + 1

Step 3: STACK [TOP] = X

Algorithm for POP Operation

Step 1: If TOP = -1 then

       Write "Stack is Underflow"

Step 2: Return STACK [TOP]

Step 3: TOP = TOP - 1

Peek, isempty, isfull Operation

- **isfull():**
  - if top equals to MAXSIZE
  - return true
  - else
  - return false
  - endif
- **isempty():**
  - if top less than 1
 - return true
  - else
  - return false
  - endif
- **peek():**
  - return stack[top]

QUEUE

✂ Queue is also an abstract data type or a linear data structure, in which the first element is inserted from one end called REAR(also called tail), and the deletion of exisiting element takes place from the other end called as FRONT(also called head). This makes queue as FIFO data structure, which means that element inserted first will also be removed first.

✂ The process to add an element into queue is called Enqueue and the process of removal of an element from queue is called Dequeue.

enqueue() operation   dequeue() operation

REAR   FRONT

enqueue( ) is the operation for adding an element into Queue.

dequeue( ) is the operation for removing an element from Queue .

QUEUE DATA STRUCTURE

Queue

Basic features of Queue

✂Like Stack, Queue is also an ordered list of elements of similar data types.

✂Queue is a FIFO(First in First Out) structure.

✂Once a new element is inserted into the Queue, all the elements inserted before the new element in the queue must be removed, to remove the new element.

✂peek( ) function is oftenly used to return the value of first element without dequeuing it.

Applications of Queue

✂ Queue, as the name suggests is used whenever we need to have any group of objects in an order in which the first one coming in, also gets out first while the others wait for there turn, like in the following scenarios :

  ✂ Serving requests on a single shared resource, like a printer, CPU task scheduling etc.

  ✂ In real life, Call Center phone systems will use Queues, to hold people calling them in an order, until a service representative is free.

  ✂ Handling of interrupts in real-time systems. The interrupts are handled in the same order as they arrive, First come first served.

  ✂ A real world example of queue can be a single-lane one-way road, where the vehicle enters first, exits first. More real-world example can be seen as queues at ticket windows & bus-stops.

Implementation of Queue

✂Queue can be implemented using an Array, Stack or Linked List. Initially the head(FRONT) and the tail(REAR) of the queue points at the first index of the array (starting the index of array from 0). As we add elements to the queue, the tail keeps on moving ahead, always pointing to the position where the next element will be inserted, while the head remains at the first index.

✂When we remove element from Queue, we can follow two possible approaches (mentioned [A] and [B] in above diagram). In [A] approach, we remove the element at head position, and then one by one move all the other elements on position forward. In approach [B] we remove the element from head position and then move head to the next position.

Implementation of Queue
Basic Operations

✂ Queue operations may involve initializing or defining the queue, utilizing it and then completing erasing it from memory. Here we shall try to understand basic operations associated with queues −

- enqueue() − add (store) an item to the queue.

- dequeue() − remove (access) an item from the queue.

✂ Few more functions are required to make above mentioned queue operation efficient. These are −

- peek() − get the element at front of the queue without removing it.

- isfull() − checks if queue is full.

- isempty() − checks if queue is empty.

✂ In queue, we always dequeue (or access) data, pointed by front pointer and while enqueing (or storing) data in queue we take help of rear pointer.

Basic Operations

- **peek():**
  return queue[front]

- **isfull():**
  if(rear == MAXSIZE - 1)
      return true;
  else
      return false;
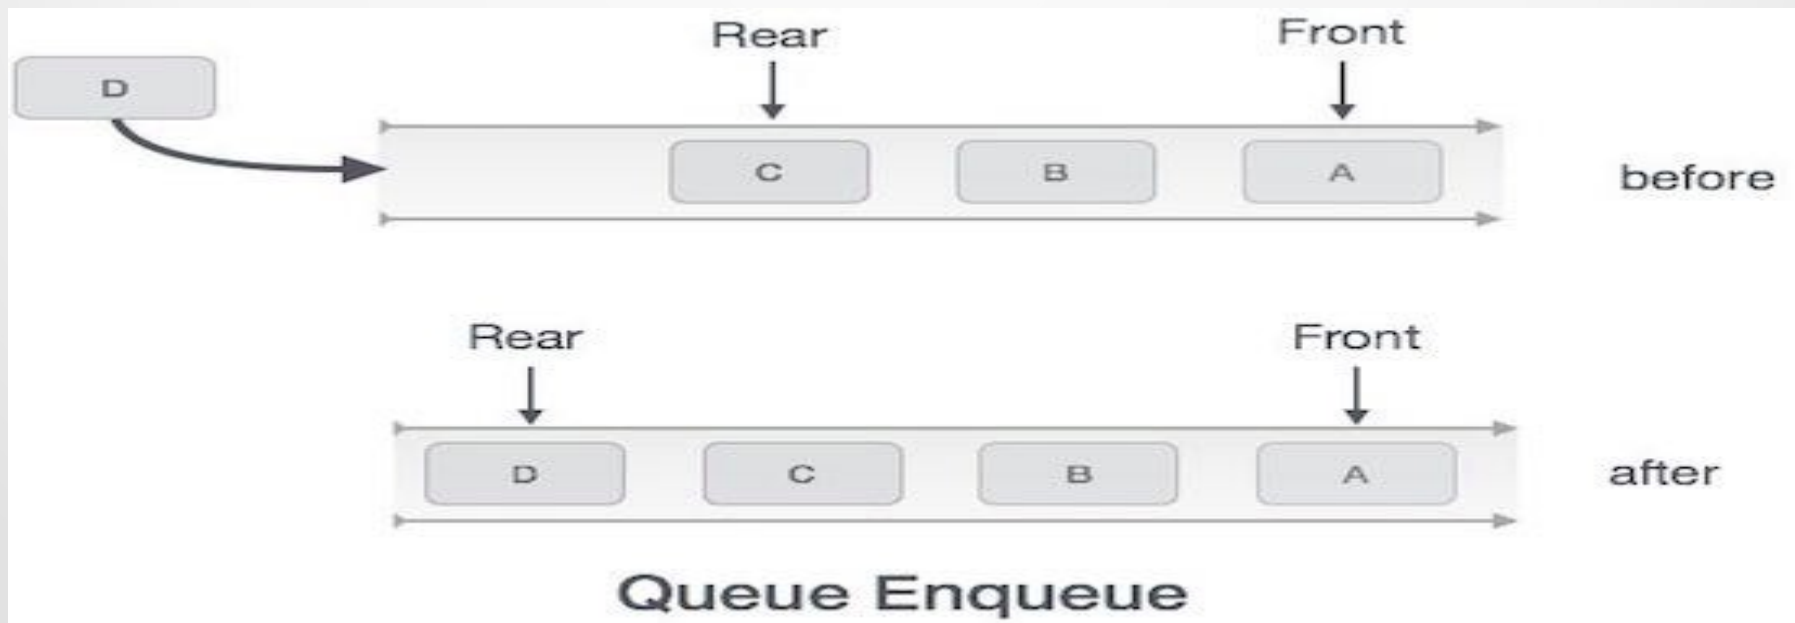

- **isempty():**
  if(front < 0 || front > rear)
      return true;
  else
      return false;

Enqueue Operation

�苦Step 1 − Check if queue is full.
✿Step 2 − If queue is full, produce overflow error and exit.
✿Step 3 − If queue is not full, increment rear pointer to point next empty space.
✿Step 4 − Add data element to the queue location, where rear is pointing.
✿Step 5 − return success.

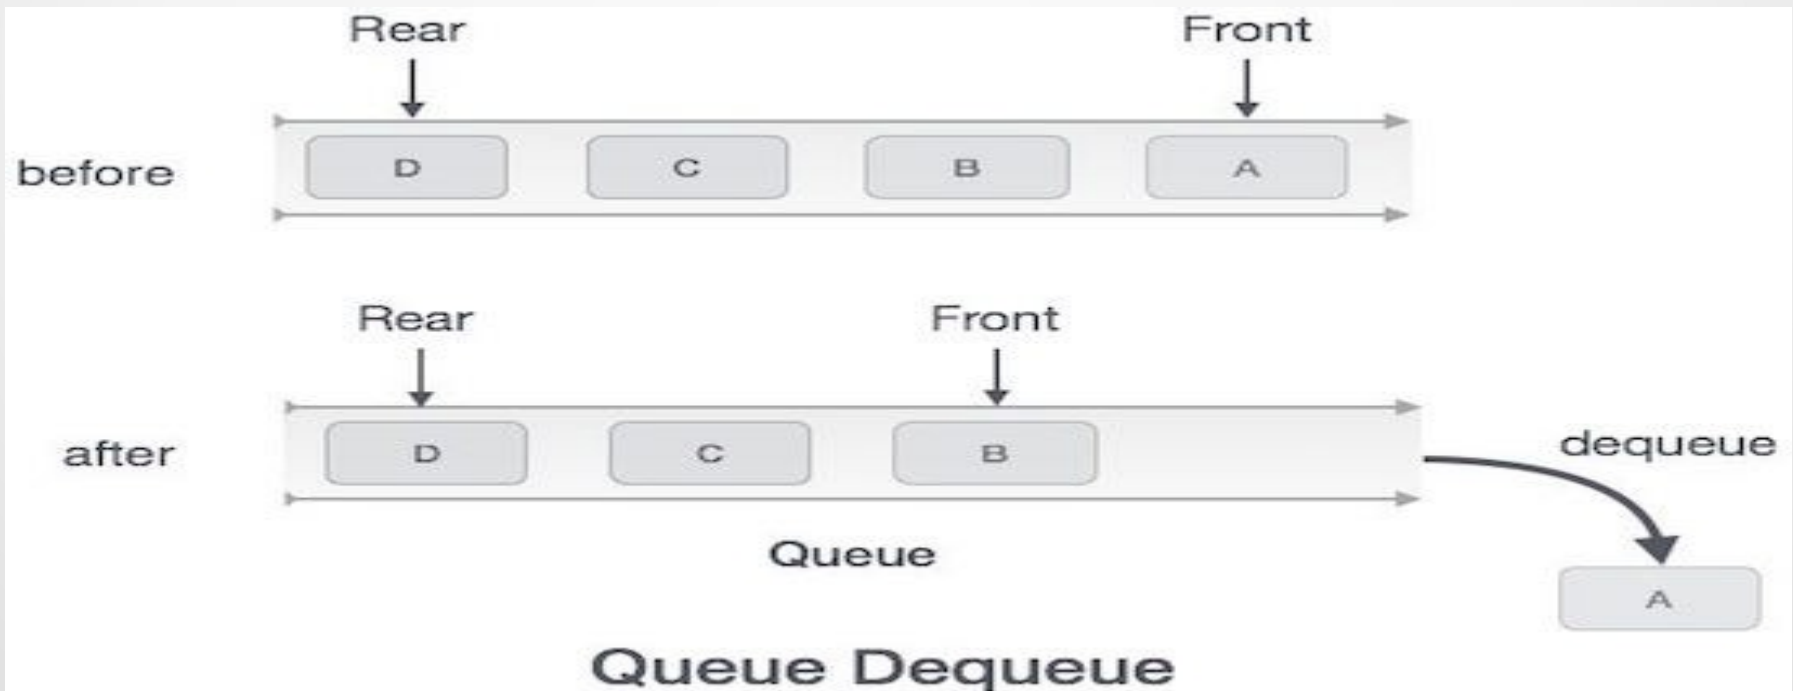

Queue Enqueue

Enqueue Operation

Algorithm/Logic:

```
if(isfull())
      return 0;

   rear = rear + 1;
   queue[rear] = data;

   return 1;
```

Dequeue Operation

✂ Step 1 − Check if queue is empty.
✂ Step 2 − If queue is empty, produce underflow error and exit.
✂ Step 3 − If queue is not empty, access data where front is pointing.
✂ Step 3 − Increment front pointer to point next available data element.
✂ Step 5 − return success.

Queue Dequeue

Dequeue Operation

Algorithm/Logic:
if(isempty())
    return 0;

 int data = queue[front];
  front = front + 1;

  return data;

Types of Queue

✂ **Queue can be of four types:**

 1. Simple Queue

 2. Circular Queue

 3. Priority Queue

 4. Dequeue (Double Ended queue)

Types of Queue

1. Simple Queue: In Simple queue Insertion occurs at the rear of the list, and deletion occurs at the front of the list.

Types of Queue

2. Circular Queue : A circular queue is a queue in which all nodes are treated as circular such that the first node follows the last node.
Circular Queue is a linear data structure in which the operations are performed based on FIFO (First In First Out) principle and the last position is connected back to the first position to make a circle.
Types of Queue

✂In a normal Queue Data Structure, we can insert elements until queue becomes full. But once if queue becomes full, we can not insert the next element until all the elements are deleted from the queue. For example consider the queue below...

✂After inserting all the elements into the queue.

Types of Queue

✂ Now consider the following situation after deleting three elements from the queue.

This situation also says that Queue is Full and we can not insert the new element because, 'rear' is still at last position. In above situation, even though we have empty positions in the queue we can not make use of them to insert new element. This is the major problem in normal queue data structure. To overcome this problem we use circular queue data structure.

Types of Queue

✂ To implement a circular queue data structure using array, we first perform the following steps before we implement actual operations.

- **Step 1:** Include all the header files which are used in the program and define a constant 'SIZE' with specific value.
- **Step 2:** Declare all user defined functions used in circular queue implementation.
- **Step 3:** Create a one dimensional array with above defined SIZE (int cQueue[SIZE])
- **Step 4:** Define two integer variables 'front' and 'rear' and initialize both with '-1'. (int front = -1, rear = -1)
- **Step 5:** Implement main method by displaying menu of operations list and make suitable function calls to perform operation selected by the user on circular queue

Types of Queue

✂ **enQueue(value) - Inserting value into the Circular Queue**

✂ In a circular queue, enQueue() is a function which is used to insert an element into the circular queue. In a circular queue, the new element is always inserted at rear position. The enQueue() function takes one integer value as parameter and inserts that value into the circular queue. We can use the following steps to insert an element into the circular queue...

✂   Step 1: Check whether queue is FULL. ((rear == SIZE-1 && front == 0) || (front == rear+1))

✂   Step 2: If it is FULL, then display "Queue is FULL!!! Insertion is not possible!!!" and terminate the function.

✂   Step 3: If it is NOT FULL, then check rear == SIZE - 1 && front != 0 if it is TRUE, then set rear = -1.

✂   Step 4: Increment rear value by one (rear++), set queue[rear] = value and check 'front == -1' if it is TRUE, then set front = 0.

Types of Queue

✄**deQueue() - Deleting a value from the Circular Queue**

✄In a circular queue, deQueue() is a function used to delete an element from the circular queue. In a circular queue, the element is always deleted from front position. The deQueue() function doesn't take any value as parameter. We can use the following steps to delete an element from the circular queue...

✄   Step 1: Check whether queue is EMPTY. (front == -1 && rear == -1)

✄   Step 2: If it is EMPTY, then display "Queue is EMPTY!!! Deletion is not possible!!!" and terminate the function.

✄   Step 3: If it is NOT EMPTY, then display queue[front] as deleted element and increment the front value by one (front ++). Then check whether front == SIZE, if it is TRUE, then set front = 0. Then check whether both front - 1 and rear are equal (front -1 == rear), if it TRUE, then set both front and rear to '-1' (front = rear = -1).

Types of Queue

✂ **display() - Displays the elements of a Circular Queue**
✂ We can use the following steps to display the elements of a circular queue...

✂   Step 1: Check whether queue is EMPTY. (front == -1)
✂   Step 2: If it is EMPTY, then display "Queue is EMPTY!!!" and terminate the function.
✂   Step 3: If it is NOT EMPTY, then define an integer variable 'i' and set 'i = front'.
✂   Step 4: Check whether 'front <= rear', if it is TRUE, then display 'queue[i]' value and increment 'i' value by one (i++). Repeat the same until 'i <= rear' becomes FALSE.
✂   Step 5: If 'front <= rear' is FALSE, then display 'queue[i]' value and increment 'i' value by one (i++). Repeat the same until 'i <= SIZE - 1' becomes FALSE.
✂   Step 6: Set i to 0.
✂   Step 7: Again display 'cQueue[i]' value and increment i value by one (i++). Repeat the same until 'i <= rear' becomes FALSE

Types of Queue

3. Priority Queue: A priority queue is a queue that contains items that have some preset priority. When an element has to be removed from a priority queue, the item with the highest priority is removed first.
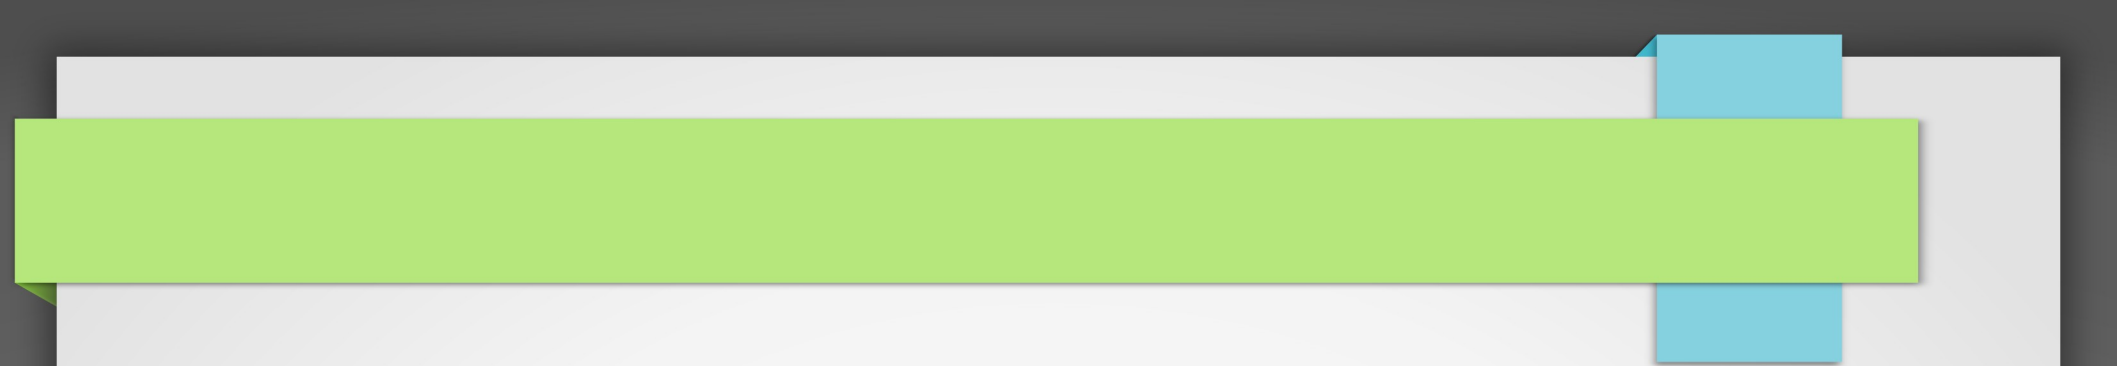

Types of Queue

4. Dequeue (Double Ended queue): In dequeue(double ended queue) Insertion and Deletion occur at both the ends i.e. front and rear of the queue.
Double Ended Queue is also a Queue data structure in which the insertion and deletion operations are performed at both the ends (front and rear).

That means, we can insert at both front and rear positions and can delete from both front and rear positions.
Double Ended Queue can be represented in TWO ways, those are as follows...

Input Restricted Double Ended Queue

Output Restricted Double Ended Queue

Input Restricted Double Ended Queue

In input restricted double ended queue, the insertion
operation is performed at only one end and deletion
operation is performed at both the ends.

Output Restricted Double Ended Queue

In output restricted double ended queue, the deletion operation is performed at only one end and insertion operation is performed at both the ends.
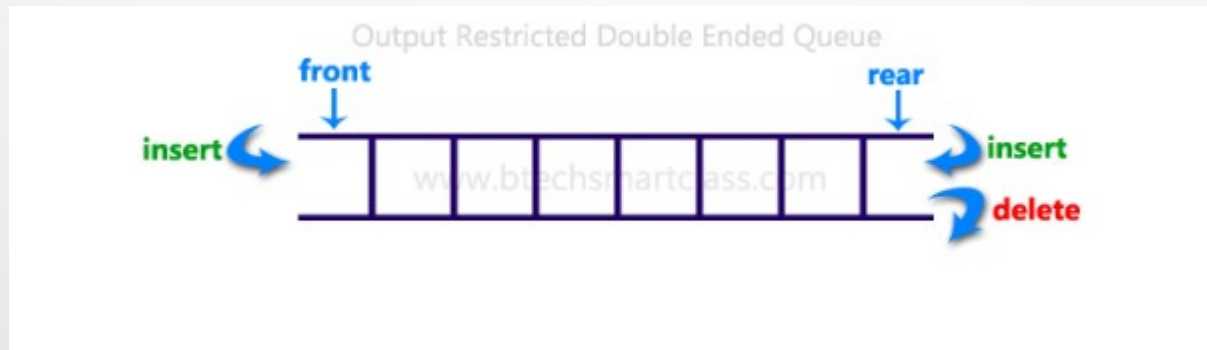

Applications of Queue

- Applied as waiting lists for a single shared resource like CPU, Disk, Printer.

- Applied as buffers on MP3 players and portable CD players.

- Applied on Operating system to handle interruption.

- Applied to add song at the end or to play from the front.

- Applied on WhatsApp when we send messages to our friends and they don't have an internet connection then these messages are queued on the server of WhatsApp.
